AHA-ACC 2004 STEMI guidelines
Hospitalizations in the U.S. Due to Acute Coronary Syndromes (ACS)

1.57 Million Hospital Admissions - ACS

UA/NSTEMI†
1.24 million Admissions per year

STEMI
.33 million Admissions per year

*Primary and secondary diagnoses. †About 0.57 million NSTEMI and 0.67 million UA.
STEMI
Case

A 56 year old male with no PMH presents with sudden onset of severe crushing retrosternal chest pain that woke him from sleep. It radiated down his left arm. It was accompanied with sweating, and shortness of breath.
Physical Examination

- HR 70/min, BP 130/80, RR 22/min
- JVP not raised
- Chest clear
- Normal S1 and S2, ?S3
- Soft non tender abdomen
- No LE edema
Differential Diagnosis of Acute Chest Pain

Cardiac
- ACS
- Aortic Dissection*
- Pericarditis

Pulmonary
- Pulmonary Embolism*
- Pneumonia
- Pneumothorax*

- Chest wall
  - Rib fracture
  - Costochondritis
  - Herpes zoster (before rash)

- Gastrointestinal
  - Biliary
  - Esophageal
    - Spasm
    - Rupture
  - Pancreatitis
  - Peptic Ulcer*
Pneumothorax
Pulmonary Embolism

Large thrombus
Aortic Dissection
Figure 3. Pathway For Diagnosis Of ST-Segment Elevation Myocardial Infarction

1. **Patient presents with symptoms suggestive of a STEMI**
2. **Perform ECG within 10 minutes**
3. **Initiate IV access, monitor cardio-respiratory status, and perform history and focused physical examination.**

**ST-segment elevation?**

- **YES**
  - **Repeat the ECG; send cardiac biomarkers.**
  - **NO**
    - **Any ECG changes?**
      - **YES**
        - **Consider other ACS and non-ACS conditions.**
        - **Repeat ECGs and reevaluate.**
        - **Send and monitor cardiac enzymes.**
        - **Conduct more extensive patient history and physical examination.**
      - **NO**
        - **Meets STEMI diagnostic criteria?**
          - **YES**
            - **STEMI!**
              - **Start Initial Therapies**
                - **Oxygen**
                  - Give to patients with oxygen saturation < 90%; use with caution in patients with congestive heart failure or COPD.
                - **Aspirin**
                  - 325 mg chewed, before or within 30 min of arrival
                - **Nitroglycerin**
                  - 0.4-mg SL tablets every 3-5 min up to 3 times; if effect is not sustained, can continue with an IV drip of 50 mg in 250-mL D5W, run at 10-20 mcg/min, then titrated to effect
                - **Morphine**
                  - Still recommended by the ACC/AHA as an initial therapy; however, a notable 2005 trial found its use associated with increased mortality.** Give in multiple 2-mg doses and titrate upward, along with nitroglycerin, until patient is pain free.
              - **Provide thrombolytics within 30 minutes or perform PCI within 60 minutes.**
ECG Criteria for STEMI

- **New ST elevation**
  - $>0.1$ mV in 2 contiguous leads
  - Any 2 (II, III, aVF) or ($V_2$-$V_6$, I, aVL)
  - Not aVR or V1

- **In $V_2$ & $V_3$**
  - $\geq 0.2$ mV in men
  - $\geq 0.15$ mV in women

- **New LBBB**

Thygesen et al. Universal Definition of MI
Proposed Criteria to determine who gets ECG in ER STAT

- >30 with chest pain
- >50 with dyspnea, altered mental status, upper extremity pain, syncope or weakness
- >80 with abdominal pain, nausea and vomiting

DOESN'T REPLACE CLINICAL JUDGEMENT

Not Every ST Elevation is a STEMI!!!
Early Repolarization
Pericarditis
Left Bundle Branch Block
Back to our patient - ECG

PATIENT HAS A STEMII!!!
STEMI PRE HOSPITAL RX GOALS

• Delivery patients to an appropriate health facility as quickly as possible
• Preventing sudden death and controlling arrhythmia using ACLS when necessary
• Initiating and continuing management of patients during inter facility transfer
Important direct signout from EMS team

- Person who initiated EMS involvement and why
- Complaints at the scene
- Vital signs, physical exam, and notable changes
- Therapies prior to arrival and patient response
- ECGs from outside and en route
- Code status
- Family contact for supplemental information
Management

Initial measures
- IV access
- Continuous cardiac monitoring
- Oxygen

Reperfusion therapy
- Fibrinolysis
- Primary PCI
- Bypass Surgery

Medication
- Antiplatelet Agents
- Anticoagulants
- Beta Blockers
- Statin
General Therapy
General Therapy

- **MONA**
  - Morphine (q 5-15 min CLASS I)
  - Oxygen (pulse ox>90% CLASS I)
  - Nitroglycerin (0.4 mg SL NTG x 3 for ischemic pain CLASS I)
  - Aspirin
Aspirin

- Aspirin should be chewed by patients who have not taken aspirin before presentation with STEMI. The initial dose should be 162 mg (Level of Evidence: A) to 325 mg (Level of Evidence: C). Class I

- In a dose of 162 mg or more, aspirin produces a rapid clinical antithrombotic effect caused by immediate and near-total inhibition of thromboxane A2 production. (ISIS-2-->ASA led to 23% reduction in mortality):

Beta-Blockers
Beta-Blockers

Recommendations - Class Ia (B)

- **ORAL** beta-blocker therapy **SHOULD BE** initiated in the first 24 hours for patients who **DO NOT** have any of the following:
  1) signs of heart failure,
  2) evidence of a low output state,
  3) increased risk for cardiogenic shock, or
  4) relative contraindications to beta blockade
    - 1AVB > 0.24 sec,
    - 2\textsuperscript{nd} or 3\textsuperscript{rd}-degree heart block
    - reactive airway disease

**There is no study evaluating oral beta blockers alone**

*Risk factors for cardiogenic shock: heart failure, age > 70, systolic blood pressure < 120, sinus tachycardia > 110 or heart rate < 60, increased time since onset of STEMI symptoms*
Recommendations - Class IIa (B)

• It is reasonable to administer an **IV BETA BLOCKER** at the time of presentation to STEMI patients who are **HYPERTENSIVE** and who do not have any of the following:
  1) signs of heart failure,
  2) evidence of a low output state,
  3) increased risk for cardiogenic shock, or
  4) relative contraindications to beta blockade
    - 1AVB > 0.24 sec,
    - 2\textsuperscript{nd}- or 3\textsuperscript{rd}-degree heart block
    - reactive airway disease

*Risk factors for cardiogenic shock: heart failure, age > 70, systolic blood pressure < 120, sinus tachycardia > 110 or heart rate < 60, increased time since onset of STEMI symptoms*
Recommendations - Class III (A)

• IV beta blockers **SHOULD NOT** be administered to STEMI patients who have any of the following:

  1) signs of heart failure
  2) evidence of a low output state
  3) increased risk* for cardiogenic shock
  4) relative contraindications to beta blockade
     ➢ 1AVB > 0.24 sec,
     ➢ 2nd- or 3rd-degree heart block
     ➢ reactive airway disease

*Risk factors for cardiogenic shock: heart failure, age > 70, systolic blood pressure < 120, sinus tachycardia > 110 or heart rate < 60, increased time since onset of STEMI symptoms
Reperfusion
“Time is Muscle”
Mortality with TIMI Flow

![Bar chart showing 30-day mortality for TIMI 0,1, 2, and 3 categories](image)
Reperfusion

- STEMI patients presenting to a hospital with PCI capability should be treated with primary PCI **within 90 min** of first medical contact as a systems goal. **Class Ia**

- STEMI patients presenting to a hospital without PCI capability, and who cannot be transferred to a PCI center and undergo PCI within 90 min of first medical contact, should be treated with fibrinolytic therapy **within 30 min** of hospital presentation as a systems goal, unless fibrinolytic therapy is contraindicated. **Class Ib**
PCI vs Fibrinolysis for STEMI: Short-Term Clinical Outcomes

Brief Review of Thrombolytic Trials

GISSI-1: Streptokinase 18% reduction in mortality at 21 d

GUSTO-1: tPA. 15% reduction in 30-day mortality compared to Streptokinase

GUSTO-3: Reteplase had no benefit over tPA but is easier to use (double bolus)

ASSENT: TNKase is similar to tPA but with less non-cerebral bleeding and better mortality with symptoms>4 hrs: Single bolus, fibrin selective, resistance to PAI-1

*Overall risk of ICH is 0.7%; Strokes occurred in 1.4%
Contraindications

- Absolute Contraindications
  - Intracranial neoplasm
  - Recent (<3 months) intracranial surgery or trauma
  - Recent (<3 months) ischemic stroke
  - h/o hemorrhagic stroke
  - Active or recent bleeding
Relative Contraindications

- BP > 180 systolic
- H/o ischemic stroke
- Recent (<4 weeks) internal bleeding
- Thrombocytopenia
Additional Notes

Treatment window
- Within 12 hours of onset of chest pain
- Never give after 24 hours
- If ongoing chest pain after 12 hours and low risk of bleeding may give thrombolysis

Success of thrombolysis is assessed by
- Resolution of Chest pain
- >50% reduction in ST elevation
- Development of accelerated idioventricular rhythm
50% reduction in mortality with lytics if given promptly
Fibrinolytics-Risk of ICH

- Elderly
- <70kg
- Uncontrolled hypertension
- Lowest risk with streptokinase
Anticoagulants

• Patients undergoing reperfusion with fibrinolytics should receive anticoagulant therapy for a minimum of 48 hours (unfractionated heparin) or up to 8 days.

• Anticoagulant regimens with established efficacy include:
  ♥ UFH (LOE: C)
  ♥ Enoxaparin (LOE:A)
  ♥ Fondaparinux (LOE:B)
Primary Percutaneous Coronary Intervention

- Superior to thrombolysis in most cases
- Less reinfarction, death
- Less stroke, bleeding
2013 STEMI guideline

• Primary PCI is the preferred treatment for STEMI
  – At a hospital with PCI, the goal is PCI within **90 minutes**
  – At a hospital without PCI, the goal is transfer and PCI within **120 minutes**
  – If transfer for PCI within 120 minutes is not feasible, use fibrinolytic therapy unless contraindicated, with a door-to-needle time less than **30 minutes**

2013 STEMI guideline

• Patients with cardiogenic shock or severe HF should be transferred immediately for PCI

• Patients who have failed to reperfuse with fibrinolytic therapy should be transferred urgently for PCI

• Therapeutic hypothermia is recommended for comatose patients with STEMI and cardiac arrest

Coronary Angiography

1

2

3
Normal Coronary Angiogram

- LAD
- LMT
- LCx
- Septal Perforators
- Obtuse Marginal

RAO 20° Caudal 20°
After STEMI Care

- All patients should be admitted to a bed with continuous cardiac monitoring
- All patients should be given (if no contraindications)
  - Beta Blocker (lifelong)
  - ACE inhibitor (lifelong)
  - Statin (lifelong)
- Additional medication
  - Spironolactone (if low EF, diabetic)
Post STEMI Risk Assessment

Coronary Angiography after STEMI

- Patients who fail thrombolysis (continued chest pain, failure of ST segment resolution)
- Patients who have high risk features
  - Heart failure (either clinical or Low EF)
  - Serious Arrhythmias

Patients who don’t have high risk features after STEMI should undergo Exercise ECG stress testing for risk stratification
Complications of Myocardial Infarction

- Arrhythmias
- Ventricular Septal Perforation
- Ischemic Mitral Regurgitation, Papillary Muscle Rupture
- Ventricular Free Wall Rupture
- Systemic Embolism
- Ventricular Aneurysm
- Pericarditis
- Cardiogenic Shock (another lecture)
Ventricular Arrhythmias

- 60-110 BPM; Up to 20% STEMI patients have this
- Usually a result of reperfusion; no specific therapy needed if HD stable. Otherwise, atropine or even atrial pacing may increase sinus rate to overdrive pace the AIVR
- Routine post-MI management with B-blockers, ACE, etc.
PVC’s

- Extremely common, along with short runs of NSVT
- Amiodarone won’t increase mortality, other antiarrhythmics (other than B-blockers) do.
- B-blockers, electrolytes
- Best if no antiarrhythmics are used
Ischemic VT is often polymorphic; HR>100-110 BPM.
Higher risk with more LV damage and in first 2 days after MI.
Treat: DCCV, cath lab (if needed), electrolyte correction, amiodarone, lidocaine, B-Blockers.
If That Didn’t Make You Nervous...

Primary VF: Sudden event with no warning--10% STEMI patients before lytics. MUCH MUCH less now

Secondary VF: Occurring in setting HF or shock

Late VF: >48 hrs after MI-->Increased risk with IVCD, anterior wall MI, persistent SVT early in course, and RV infarction requiring pacing

***Have to worry about structural complication (free wall rupture)/ischemia

Treat: Non-synced DCCV, electrolyte correction
Why get worked up about electrolytes?

NOTE: Pre-lytic study
Sinus Bradycardia/Junctional Escape Rhythm

• 4-5% of STEMI patients have a bradyarrhythmia
• Sinus node ischemia—Blood supply to SA node is: 65% RCA, 25% LCX, 10% dual supply.
• Most commonly seen in Inferior/posterior MI’s.
• Often induced by vagal reaction that may be protective
Atrioventricular Block

- **First-Degree:** Usually the RCA and does not require treatment. Hold the B-blocker for PR > 240 ms

- **Second-Degree:** Usually RCA disease and does not require treatment unless HR less than 50 and arrhythmia or symptoms. Otherwise, atropine or pace

- **Third-Degree:** Can be from any location of infarct. Can be preceded by Mobitz II Block
  - Pace for symptoms and for hemodynamic support. Usually not needed in inferior MI’s as block is transient (pace for HR < 40-50)
Post-MI VSD

- ~2% of acute MI’s prior to reperfusion era
- ~0.2% in GUSTO-I streptokinase trial
- Without reperfusion, usually occurs within first week
  - Day 1--Large intramural hematomas that dissect
  - Day 3-5--Coagulation necrosis
- 24 hr or less if receive lysis--Lytics reduce infarct size but may promote hemorrhagic dissection of myocardium
Symptoms, Exam, and Diagnosis

• Chest pain, dyspnea

• PE: Harsh, holosystolic murmur along sternal border radiating to base/apex/R parasternum; thrill in 1/2 patients; S3; Loud P2; TR.

• Compared to acute MR, murmur is loud. Up to 20% of patients may have MR as well though
CCU Management

- IABP
- Ventilation
- Diuresis/HF Management
- Inotropes (can increase shunt)
- Nitroprusside if tolerated (can cause hypotension)
- Mortality with conservative management is HIGH (24%, 46%, 67-82% at 24 hrs, 1 wk, and 2 months, respectively)
- Ultimately, mechanical closure needed (surgery vs. percutaneous)- TIMING is questionable but clinical status should not preclude this
Acute Mitral Regurgitation

- Caused by papillary muscle ischemia or rupture (less likely). Rupture is usually partial since total is essentially incompatible with life.
- Usually in setting of inferior MI involving the posteromedial papillary muscle (single PDA blood supply as opposed to anterolateral).
- Rupture usually occurs 3-5 days post-MI and in 1% of MI’s and requires emergent operative repair (50% mortality in 24 hrs).
- Accounts for 7% of cardiogenic shock and 5% of mortality associated with acute MI.
- Area of infarction does NOT have to be large.
Symptoms, Exam, Diagnosis

• Symptoms: Those of heart failure

• PE: May or may not hear loud systolic murmur (need a gradient)
CCU Management

• Mechanical ventilation if needed
• IABP—especially for hypotension
• PCI if papillary m. ischemia (not rupture)
• Afterload reduction (nitroprusside if possible) to MAP of 70-80 mm Hg
• Since mortality is 90% with medical therapy alone, surgery is the major therapy of choice
  – Perioperative mortality 20-25%
  – Overall surgical mortality is even higher
Free Wall Rupture

- ~10% of patients who die in hospital from STEMI
- Most commonly between 1 and 4 days (up to 3 weeks)
- Caused by tear or dissecting hematoma
- More common with fibrinolysis compared to PCI
- More common in patients without previous infarction
Symptoms, Exam, Diagnosis

- Acute symptoms include sudden chest pain (esp with cough, strain) and sudden death

- Subacute symptoms: Pericarditis-like symptoms (chest pain, nausea, vomiting)

- Exam (think HF and tamponade): JVD, pulsus, diminished heart sounds, rub, possibly a new murmur
Treatment

- Pericardiocentesis if time
- Surgical repair is the only treatment
- Mortality is reasonable if patient gets to the OR in time
- 90% mortality without surgery
Summary of Acute STEMI Complications

• Much more rare in the reperfusion era
  – Look for them especially in delayed presentation

• Arrhythmias are most common complication and may require emergent treatment

• VSD’s, papillary muscle rupture, and free wall ruptures carry a VERY high mortality and require emergent surgical consultation
  – Support mechanically until patient receives operation
Treatment of ACS

**UA/NSTEMI**
- Usually due to plaque rupture with partial occlusion
- Treatment options:
  - Early PCI (< 24 hrs)
  - Delayed PCI (> 24 hrs)
  - Medical therapy

**STEMI**
- Usually due to plaque rupture with total occlusion
- Treatment options:
  - Primary PCI is preferred
  - Fibrinolytic therapy
  - Medical therapy
Initial treatment of ACS

- Aspirin at initial presentation
- $\text{P2Y}_{12}$ inhibitor (clopidogrel, ticagrelor, . . .)
- Statin (atorvastatin 80 mg daily)
- Anticoagulation (heparin, enoxaparin, . . .)
- Nitrates / morphine for chest pain
- **Revascularization**

- Scenarios:
  - STEMI with PCI available
  - STEMI with PCI unavailable
  - High-risk UA/NSTEMI
  - Low-risk UA/NSTEMI
Initial treatment for STEMI with PCI available

- PCI with 90 minutes, or transfer for PCI within 120 min
- Aspirin 325 mg
- P2Y$_{12}$ inhibitor
  - Ticagrelor 180 mg
  - Prasugrel 60 mg
  - Clopidogrel 600 mg
- Anticoagulant
  - Heparin 70 units/kg
  - Bivalirudin (usually started in the cath lab)
- High dose statin (atorvastatin 80 mg)
Initial treatment for STEMI with PCI unavailable

- Fibrinolytic therapy within 30 minutes
- Aspirin 325 mg
- Clopidogrel
  - initial dose 300 mg for patients < 75 years old
  - initial dose 75 mg for patients ≥ 75 years old
- Enoxaparins, fondaparinux, or heparin
- High dose statin

**Targets**

**Goals**

- Onset of symptoms of STEMI
- 9-1-1 EMS Dispatch
- EMS on-scene
  - Encourage 12-lead ECGs
  - Consider prehospital fibrinolytic if capable and EMS-to-needle within 30 min
- EMS Transport
  - EMS-to-Balloon within 90 min
- Total ischemic time: Within 120 min

*Golden Hour = First 60 minutes*
